Brief description of the project:

The **Kidney Disease Prediction System** is a machine learning model designed to help identify the likelihood of Chronic Kidney Disease (CKD) at an early stage. By analysing key health indicators such as blood pressure, glucose, haemoglobin, and other clinical parameters, the system provides a quick and accessible way to assess a patient's risk. The goal of this project is to support early screening and awareness, making it easier for individuals and healthcare learners to understand potential risks. The tool is intended for educational and research purposes, highlighting how modern technology can assist in improving healthcare decision-making.
